1 Introduction

This text will describe an algorithm for solving systems of linear equations of the form:

$$\begin{bmatrix} a_{00} & a_{01} & \dots & a_{0k} & 0 & \dots & 0 \\ a_{10} & a_{11} & \dots & a_{1k} & a_{1(k+1)} & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ a_{k0} & a_{k1} & \dots & a_{kk} & a_{k(k+1)} & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & \dots & 0 & 0 & \dots & a_{(N-k)(N-1)} \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & \dots & 0 & 0 & \dots & a_{(N-2)(N-1)} \\ 0 & 0 & \dots & 0 & 0 & \dots & a_{(N-1)(N-1)} \end{bmatrix} \begin{bmatrix} x_0 \\ x_1 \\ x_2 \\ x_3 \\ x_4 \\ \dots \\ x_{N-2} \\ x_{N-1} \end{bmatrix} = \begin{bmatrix} b_0 \\ b_1 \\ b_2 \\ b_3 \\ b_4 \\ \dots \\ b_{N-2} \\ b_{N-1} \end{bmatrix} \quad (1)$$

For ease of representation and analysis, each diagonal will be considered as a one-dimensional array, which must be supplemented with zero elements until it reaches length N , if we are talking about the upper diagonal, or from the beginning, if we are talking about the lower diagonal:

$$\begin{cases} U_{ji} = a_{i(j+i)}, & 0 \leq i \leq N-j, & U_{ji} = 0, & N-j+1 \leq i \leq N-1, & \text{where } 1 \leq j \leq k \\ L_{ji} = 0, & 0 \leq i \leq j-1, & L_{ji} = a_{(j+i)i}, & j \leq i \leq N-1, & \text{where } 1 \leq j \leq k \end{cases} \quad (2)$$

Then the system of equations can be rewritten in a simple form:

$$\sum_{l=1}^k L_{li} x_{(i-l)} + a_{ii} x_i + \sum_{l=1}^k U_{li} x_{(i+l)} = b_i, \quad \text{where } 0 \leq i \leq N-1 \quad (3)$$

In this form, x has indices that go beyond the formal limits of $0, N-1$, but this is not so important given the zero values of the coefficients at these points. As mentioned earlier, a_{ii} is not zero, so we divide the corresponding equations by them:

$$\sum_{l=1}^k L_{li} x_{(i-l)} + x_i + \sum_{l=1}^k U_{li} x_{(i+l)} = b_i, \quad \text{where } 0 \leq i \leq N-1 \quad (4)$$

where used the new definition of U and L :

$$\begin{cases} U_{ji} = a_{i(j+i)}/a_{ii}, & 0 \leq i \leq N-j, & U_{ji} = 0, & N-j+1 \leq i \leq N-1, & \text{where } 1 \leq j \leq k \\ L_{ji} = 0, & 0 \leq i \leq j-1, & L_{ji} = a_{(j+i)i}/a_{ii}, & j \leq i \leq N-1, & \text{where } 1 \leq j \leq k \end{cases} \quad (5)$$

We will express x_i in terms of a linear combination of x_{i+1}, \dots, x_{i+k} :

$$x_i = \sum_{l=1}^k P_{il} x_{i+l} + R_i \quad (6)$$

For $i = 0$, the values of P and R are obviously expressed in terms of U and b :

$$P_{0l} = U_{0l}, \quad 1 \leq l \leq k, \quad R_0 = b_0 \quad (7)$$

For the remaining i , we introduce additional values Q^i and W^i in such a way that:

$$x_{i-l} = \sum_{j=0}^{k-1} Q_{lj}^i x_{i+j} + W_l^i \quad (8)$$

For $l = 1$:

$$x_{i-1} = \sum_{j=0}^{k-1} P_{(i-1)(j+1)} x_{i+j} + R_{i-1} \quad (9)$$

Where do we find Q_1^i and W_1^i :

$$Q_{1j}^i = P_{(i-1)(j+1)}, \quad 0 \leq j \leq k-1, \quad W_1^i = R_{i-1} \quad (10)$$

Returning to the form (6) and decomposing the sum into two parts (after x_i and before).

$$\begin{aligned} x_{i-l} &= \sum_{j=0}^{k-1} P_{(i-l)(j+1)} x_{i-l+j+1} + R_{i-l} = \\ &= R_{i-l} + \sum_{j=l}^{k-1} P_{(i-l)(j+1)} x_{i-l+j+1} + P_{(i-l)(l)} x_i + \sum_{j=0}^{l-2} P_{(i-l)(j+1)} x_{i-l+j+1} \end{aligned} \quad (11)$$

Now we use (8) for x in the second sum:

$$\begin{aligned} x_{i-l} &= R_{i-l} + \sum_{j=0}^{k-1-l} P_{(i-l)(l+j+1)} x_{i+j+1} + P_{(i-l)(l)} x_i + \\ &\quad + \sum_{j=0}^{l-2} P_{(i-l)(j+1)} \left(\sum_{p=0}^{k-1} Q_{(l-j-1)p}^{i-(l-j-1)} x_{i+p} + W_{l-j-1}^{i-(l-j-1)} \right) \end{aligned} \quad (12)$$

As a result, we get the expression for $Q_{l(\cdot)}^i$ and W_l^i through Q_{l-p}^i , W_{l-p}^i , $P_{(i-p)(\cdot)}$ and R_{i-p} where $1 \leq p$:

Now let's go back to the form (4), rewriting it as:

$$x_i = b_i - \sum_{l=1}^k U_{li} x_{(i+l)} - \sum_{l=1}^k L_{li} x_{(i-l)} = b_i - \sum_{l=1}^k U_{li} x_{(i+l)} - \sum_{l=1}^k L_{li} \left(\sum_{j=0}^{k-1} Q_{lj}^i x_{i+j} + W_l^i \right) \quad (13)$$

Moving all x_i to the left side, we find the new $P_{(i)(\cdot)}$ and R_i :

$$x_i \left(1 + \sum_{l=1}^k L_{li} Q_{l0}^i \right) = b_i - \sum_{l=1}^k U_{li} x_{(i+l)} - \sum_{l=1}^k L_{li} \left(\sum_{j=1}^{k-1} Q_{lj}^i x_{i+j} + W_l^i \right) \quad (14)$$

For $i = N-1$:

$$x_{N-1} = \left(b_{N-1} - \sum_{l=1}^k L_{l(N-1)} W_l^{N-1} \right) / \left(1 + \sum_{l=1}^k L_{l(N-1)} Q_{l0}^{N-1} \right) \quad (15)$$

Knowing x_{N-1} and $P_{i(\cdot)}$, R_i you can restore all x_i in reverse order. Thus, to calculate N values, it is necessary to calculate the order of $\sim k^2$ auxiliary values at each step, hence the total complexity of the algorithm:

$$O(Nk^2) \quad (16)$$

Since the usual algorithms for direct solution of systems of linear equations have complexity $O(N^3)$, the resulting algorithm is efficient for any k .
